(54) Composition for reversibly absorbing and desorbing hydrogen.

(57) A composition for reversibly absorbing and desorbing hydrogen, comprising 0.8 - 20% by weight of one or more oxides of one or more elements selected from La, Ce, Nd, Pr, Sm and Eu, in ZrV (wherein x is in the range 0.01 × 0.7).

EP 0 184 427 A2

Composition for Reversibly Absorbing and Desorbing Hydrogen

This invention relates to a composition for reversibly absorbing and desorbing hydrogen and isotopes thereof. In particular, the invention relates to a substance for reversibly absorbing-desorbing hydrogen and isotopes thereof which is easy
5 to hydrogenate and has a high hydrogen absorbing and desorbing rate. The composition may also be used as a 'getter' for other gases.

Hydrogen getting substances, such as Ti, Zr, Hf and the like, showing a hydrogen dissociation pressure lower than
10 atmospheric pressure at a temperature of less than 300°C have been known. However, these metals are generally covered by strong oxides and/or nitride films, so that to obtain a hydrogen-gettable clean active surface, pretreatment is required, for example, by sublimation in a sputtering method, or heat-treatment
15 at a high temperature e.g. 700 - 1,000°C.

It has been proposed to improve a pretreatment by activation with one or more additional elements to form an alloy, and so control the hydrogen dissociation pressure characteristic or increase the reversible hydrogen absorbing-desorbing rate.

20 However, Zr-Al, Zr-Ni alloys, for example, require heat-treatment or activation at a high temperature such as 450 - 750°C. On the other hand a Zr-V alloy can reversibly absorb and desorb hydrogen without an initial activation treatment, but if such an alloy (e.g. Zr-V_{0.15}) is exposed to hydrogen gas at a
25 pressure of about 0.5 kg/cm², a high temperature for initially absorbing hydrogen of about 230°C is required and the absorption rate is slow. Further, the physical properties of the alloys are such that it is difficult to prepare them with a desired size, e.g. by cutting and crushing.

30 Intermetallic compounds, Zr-V-O and the like, stabilized by oxygen have also been proposed, but these require an activation treatment and the control of sample grain size is

difficult because of the hardness of the alloys. It has also been proposed to control hydrogen dissociation pressure, sample grain size and characteristics to gases other than hydrogen, by adding 4th and 5th elements to an alloy stabilized with oxygen and forming an intermetallic compound such as Zr-Ti-V-Fe-O. However, by increasing the kinds of additional elements, it has been difficult to regulate composition of the substance.

We have now found it possible to provide reversibly hydrogen absorbing-desorbing materials showing a hydrogen equilibrium pressure lower than atmospheric pressure with a comparatively high hydrogenation composition at a temperature of less than 300°C, the materials having a low temperature for initially absorbing hydrogen and a sufficiently fast rate of absorbing and desorbing hydrogen. In addition the materials do not require any initial activation treatment. These properties are achieved by dispersing specified amounts of one or more particular rare earth oxides into ZrV having a specified composition and forming a complex.

According to the invention, there is provided a composition for reversibly absorbing and desorbing hydrogen comprising 0.8 - 20% by weight of one or more oxides of one or more elements selected from La, Ce, Nd, Pr, Sm and Eu, in ZrV_x (wherein x is in the range $0.01 \leq x \leq 0.7$).

In the compositions of the invention, the zirconium-vanadium which forms the matrix should have a composition of $\text{ZrV}_{0.01-0.7}$.

As the amount of V in the composition of this invention is increased, the hydrogen gas activity increases and the temperature-hydrogen equilibrium pressure-composition characteristics vary. When the V content is lower than the above range, the effect of increasing the hydrogen gas activity is not so conspicuous, so that the desired properties cannot be attained, and a V content exceeding the above range is not preferable because the alloy then has a high hydrogen equilibrium

pressure at a comparatively low temperature in comparatively high hydrogenation composition.

The oxides of the elements which may be dispersed in the ZrV_x matrix are one or more oxides selected from La, Ce, Nd, Pr, Sm and Eu oxides, and the amount thereof is 0.8 - 20% by weight.

The hydrogen gas activity increases as the amount of the rare earth oxide added is increased, while the temperature-hydrogen equilibrium pressure characteristic is scarcely affected. However, when the amount added does not fall within the above range, the effect of increasing activity is not noticable, and when the amount exceeds the above range, there is no more effect on the activity and the hydrogen absorption amount is only reduced, so that neither cases are preferable.

For consistency, it is preferable that the elements of the oxides are in their most stable oxidation states, that is La_2O_3 , CeO_2 , Nd_2O_3 , Pr_6O_{11} , Sm_2O_3 and Eu_2O_3 , but there is no particular reason why oxides of lower, mixed or non-stoichiometric oxidation states cannot be used.

Various methods may be employed to manufacture the composition of the invention. The most preferable method is to prepare highly pure zirconium and highly pure vanadium and a mixture of the one or more rare earth oxides mentioned above (inclusive of Misch metal oxide) to form respective predetermined compositions and to combine them in an inert atmosphere such as argon and the like.

Alternatively, the rare earth oxides are not directly mixed, but rare earth pure metals are mixed and melted in an oxidizing atmosphere, or a small amount of oxide such as of V or Zr is mixed and melted.

In addition, the composition according to the invention may also readily act as a getter for impure gases such as oxygen, nitrogen, carbon monoxide, carbon dioxide, methane, steam and the like other than hydrogen gas. In addition, the substance according to the invention can be easily

ground as compared with Zr-V as a matrix, and is generally not too brittle, and has excessive density.

The composition according to the invention does not require any activation treatment whatever the initial hydrogen content, and the initial hydrogenation rate is large while the reversible absorbing-desorbing rate is advantageously large.

Furthermore, the composition of the invention has various advantages in that it may be readily ground; the temperature condition and the like in initial hydrogenation is optimised almost without changing the temperature-pressure-composition characteristic of the mother alloy in comparison with alloy improvement by conventional 3rd element addition; the reaction rate is increased; and it may be used as a getter for other impure gases.

With these advantages, the reversible hydrogen absorbing-desorbing composition of this invention may be advantageously used for refining and separating hydrogen gas, for hydrogen gas pressure control of vacuum machines and the like, as a hydrogen gas getter, including isotope and non-volatile getter, and the like.

Figures 1 and 2 of the accompanying drawings are characteristic diagrams showing initial activity of the composition according to the present invention, and

Figure 3 is a diagram showing equilibrium hydrogen pressure to temperature characteristics of the composition according to the present invention in case of changing hydrogenation composition.

The invention will be illustrated by referring to examples hereinafter. These examples are described with preferable specified compositions and other conditions, but these examples are for illustration only and the invention is not limited to these examples.

Examples 1-33

In order to form the compositions shown in Table 1, the following were used: Zr metal powder (purity : more than 99.7%);

V metal pieces (purity : more than 99.7%); Ce_2O_3 (purity : more than 99.0%); CeO_2 (purity : more than 99.0%); Nd_2O_3 (purity : more than 99.0%); Pr_6O_{11} (purity: more than 99.0%); Sm_2O_3 (purity : more than 99.0%); Eu_2O_3 (purity : more than 99.0%); and a mixed rare earth oxide (consisting of 30 wt% of La_2O_3 , 50 wt% of CeO_2 , 15 wt% of Nd_2O_3 , 4 wt% of Pr_6O_{11} and 1 wt% of Sm_2O_3). The desired amounts of the components were arc melted in an argon atmosphere and formed into a reversible hydrogen absorbing-desorbing material.

10 The thus obtained material was ground to 20 - 40 mesh, and 4 g were charged in a hydrogen absorbing-desorbing reactor, vacuum exhausted to 10^{-2} Torr.

Hydrogen having 99.9999% purity was introduced into the reactor at a pressure of about 0.5 kg/cm^2 , the material temperature was maintained at 30°C for 10 minutes and then the temperature was raised from 30°C to 300°C at a rate of 5°C/min . By measuring the sample temperature and the pressure in the reactor, the temperature and the sample started to absorb hydrogen and the initial hydrogen absorbing rate were determined. 15 Thus, the indices of the hydrogen absorption starting temperature and the absorbing rate at the time of the initial hydrogen absorption are as shown in Table 1. Further, the saturated hydrogen absorbing amount at the temperature of starting absorption of initial hydrogen in each sample (converted into 20 STP) is as shown in Table 1.

Figure 1 is a graph showing the change with time of the hydrogen pressure in a reactor when the materials of Example No. 22 (solid line (I)), Example No. 14 (solid line (II)) and $\text{ZrV}_{0.15}$ (solid line (III)) as mother alloy thereof and ground to 20 - 40 mesh are charged in the above reactor. After vacuum exhaustion of the reactor to 10^{-2} Torr, a hydrogen pressure of 0.5 kg/cm^2 is provided, 30°C is maintained for 10 minutes, and the temperature is raised to 300°C at a rate of 5°C/min . 30

In Figure 1, the abscissa indicates time, the ordinate 35 indicates the pressure in a reactor at that time by a solid line

and the temperature in the vicinity of a sample at that time by a one-dot line.

Figure 2 is a graph showing the change with time of hydrogen pressure when testing materials of Example No. 32 (solid line A), Example No. 29 (solid line B), Example No. 22 (solid line C), Example No. 8 (solid line D) and respective mother alloys $\text{ZrV}_{0.7}$ (broken line a) and $\text{ZrV}_{0.5}$ (broken line b), $\text{ZrV}_{0.15}$ (broken line c) and $\text{ZrV}_{0.1}$ (broken line d) under the same condition as in the case shown in Figure 1.

In Figure 2, the abscissa indicates time, the ordinate indicates the pressure in a reactor at that time by a solid-broken line, and the sample temperature by one-dot line.

Figure 3 is a graph showing the hydrogen pressure temperature characteristic of a sample measured by grinding the material of Example No. 22 to 20-40 mesh, weighing 4 g into a vacuum measuring hydrogen absorbing-desorbing container, continuously heating and vacuum exhausting the whole container at 250°C for 48 hours with a cryopump, thereafter sealing a sample system from the exhaust system, introducing a predetermined amount of hydrogen gas at a room temperature for absorption by the sample, raising the temperature from room temperature to about 350°C by balancing the hydrogen pressure, and returning to room temperature in the same manner.

In Figure 3, the abscissa indicates the hydrogen pressure in the container charged with the sample, that is, it shows the equilibrium hydrogen pressure of said sample at that temperature, and the ordinate shows the sample temperature at that time (shown by $(1000/T \text{ (1/k)})$ and $(^\circ\text{C})$).

In Figure 3, the solid line shows the time of absorbing hydrogen and the broken line shows the time of desorbing hydrogen, wherein (1) shows that the hydrogen content in the hydrogenated product is 5% of the saturated hydrogen absorbing amount, (2) shows 10%, and (3) shows 15%, respectively. Each example extremely quickly absorbs and desorbs hydrogen to reach

0184427

equilibrium, and shows the hydrogen pressure-temperature characteristic as shown in Figure 3.

Further, in this pressure measurement, the pressure range from 10^{-5} to 10^{-2} Pa is the partial pressure measurement of hydrogen gas, and the pressure range higher than 10^{-2} Pa is the total pressure measurement with the use of an ionizer vacuum meter.

Absorption of CO-N₂

The material of Example No. 22 was ground to 20 - 40 mesh, 4 g placed in a stainless vacuum measurement hydrogen absorbing-desorbing container (A), while a control container (B) was free of the material. Both (A) and (B) were continuously heated and vacuumed at 150°C for 24 hours with a cryopump and back to a room temperature, sealed from the exhaust system, and the change with time of respective CO-N₂ partial pressures within said containers (A) and (B) determined. At a room temperature of 23°C, the container (A) shows an increase of CO-N₂ component at a rate of 7.2×10^{-10} Torr l/sec, and the container (B) shows an increase of CO-N₂ at a ratio 1.7×10^{-9} Torr l/sec. Therefore, even at a room temperature of 23 °C, the sample absorbs the CO-N₂ content at an absorbing rate of 9.6×10^{-10} Torr l/sec. The temperatures of both the containers (A) and (B) was raised from 25°C to 250°C at a rate of 1.5°C/min, and the change with time of the CO-N₂ partial pressure was examined in the same manner as described above.

The container (A) has 2×10^{-4} Pa at a room temperature and a partial pressure of 1.2×10^{-5} Pa at 250°C, and the container (B) has 2×10^{-4} Pa at a room temperature and 2.9×10^{-2} Pa at 250°C. Therefore, it means that said sample absorbs the CO-N₂ component at 1.2×10^{-4} Torr l/sec during this period. Further, the temperature when the CO-N₂ partial pressure is reduced in the container (A) is about 40°C.

O₂ Partial Pressure

O₂ Partial pressure is investigated by leaking a small amount of oxygen into the container in a temperature range from

room temperature to 250°C. For said sample (A), O_2 partial pressure was reduced to about 1×10^{-7} Pa within one minute.

$ZrV_{0.15}Nd_2O_3$ 10 wt% and $ZrV_{0.15}Pr_6O_{11}$ 10wt% are not shown in Table 1 as examples, but are expected to obtain the same effect as that examples shown in Table 1.

The following materials may also be expected to obtain the same effect as those of examples shown in Table 1.

$ZrV_{0.15}La_2O_3$ p wt%, CeO_2 q wt%
 $ZrV_{0.15}La_2O_3$ p wt%, Nd_2O_3 q wt%
 10 $ZrV_{0.15}La_2O_3$ p wt%, Pr_6O_{11} q wt%
 $ZrV_{0.15}CeO_2$ p wt%, Sm_2O_3 q wt%
 $ZrV_{0.15}CeO_2$ p wt%, Eu_2O_3 q wt%
 $ZrV_{0.15}Nd_2O_3$ p wt%, Pr_6O_{11} q wt%
 $ZrV_{0.15}Sm_2O_3$ p wt%, Eu_2O_3 q wt%

15 (In the above materials, $0.8 \leq p + q \leq 20$)

$ZrV_{0.15}La_2O_3$ p wt%, CeO_2 q wt%
 Sm_2O_3 r wt%

(In this material, $0.8 \leq p + q + r \leq 20$)

$ZrV_{0.15}La_2O_3$ p wt%, CeO_2 q wt%
 20 Sm_2O_3 r wt%, Eu_2O_3 s wt%

(In this material, $0.8 \leq p + q + r + s \leq 20$)

$\text{ZrV}_{0.15}\text{La}_2\text{O}_3$ p wt%, CeO_2 q wt%
 Nd_2O_3 r wt%, Sm_2O_3 s wt%
 Eu_2O_3 t wt%

(In this material, $0.8 \leq p + q + r + s + t \leq 20$)

CLAIMS:

1. A composition for reversibly absorbing and desorbing hydrogen, comprising 0.8 - 20% by weight of one or more oxides of one or more elements selected from La, Ce, Nd, Pr, Sm and Eu, in ZrV_x (wherein x is in the range $0.01 \leq x \leq 0.7$).
- 5 2. A composition as claimed in claim 1, wherein the oxide component comprises one or more of La_2O_3 , CeO_2 , Nd_2O_3 , Pr_6O_{11} , Sm_2O_3 and Eu_2O_3 .
3. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises La_2O_3 (p% by weight) and
10 any one of CeO_2 , Nd_2O_3 and Pr_6O_{11} (q% by weight) where $0.8 \leq p + q \leq 20$.
4. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises CeO_2 (p% by weight) and any one of Sm_2O_3 and Eu_2O_3 (q% by weight) where $0.8 \leq p + q \leq 20$.
- 15 5. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises Nd_2O_3 (p% by weight) and Pr_6O_{11} (q% by weight) where $0.8 \leq p + q \leq 20$.
6. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises Sm_2O_3 (p% by weight) and Eu_2O_3 (q% by weight) where $0.8 \leq p + q \leq 20$.
20
7. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises La_2O_3 (p% by weight), CeO_2 (q% by weight) and Sm_2O_3 (r% by weight), where $0.8 \leq p + q + r \leq 20$.
- 25 8. A composition as claimed in either of claims 1 and 2, wherein the oxide component comprises La_2O_3 (p% by weight), CeO_2 (q% by weight), Sm_2O_3 (r% by weight) and Eu_2O_3 (s% by weight), where $0.8 \leq p + q + r + s \leq 20$.
9. A composition as claimed in either of claims 1 and 2,
30 wherein the oxide component comprises La_2O_3 (p% by weight), CeO_2 (q% by weight), Nd_2O_3 (r% by weight), Sm_2O_3 (s% by weight) and Eu_2O_3 (t%, by weight), where $0.8 \leq p + q + r + s + t \leq 20$.

10. A method of reducing the hydrogen content of a hydrogen containing atmosphere which comprises contacting said atmosphere with a composition according to any one of the preceding claims.

11. A method of purifying an impure gas which comprises
5 contacting said gas with a composition according to any one of claims 1 to 9.
